## (1) Real Party in Interest

FROM ROGITZ 619 338 8078

CASE NO.: BLD9-2000-0060-US2

Serial No.: 09/693,090 December 7, 2004

Page 2

PATENT Filed: October 20, 2000

The real party in interest is IBM Corp.

## (2) Related Appeals/Interferences

No other appeals or interferences exist which relate to the present application or appeal.

### (3) Status of Claims

Claims 1-29 are pending and finally rejected.

### (4) Status of Amendments

No amendments are outstanding.

## (5) Concise Explanation of Subject Matter in Each Independent Claim, with Page and Figure Nos.

As an initial matter, it is noted that according to the Patent Office, the concise explanations under this section are for Board convenience, and do not supersede what the claims actually state, 69 Fed. Reg. 155 (August 2004), see page 49976. Accordingly, nothing in this Section should be construed as an estoppel that limits the actual claim language.

Claim 1 recites a computer system that includes a compiler (11, second line from the bottom of page 6, Figure 1) receiving higher-level code and outputting lower-level code to enable a processor (12, id.) to simultaneously process multiple multi-bit data elements in a single register (24, Figure 3, page 9 at the top). The logic of the lower-level code includes establishing at least first and second signed, multi-bit data elements in at least a first register (block 56, Figure 7, last paragraph on page 17). The logic also includes

FROM ROGITZ 619 338 8078

CASE NO.: BLD9-2000-0060-US2

Serial No.: 09/693,090

December 7, 2004

Page 3

PATENT Filed: October 20, 2000

simultaneously processing the elements (id.) A carry and/or a borrow may occur between data elements in

a register (Figure 9, last full paragraph on page 19).

The reference numerals and page and figure numbers above are incorporated in the summary of Claim

7, which recites a computer program device that includes a computer program storage device (Figure 1, last

two lines of page 8 continuing to page 9) which is readable by a digital processing apparatus and a compiler

program on the program storage device. The program includes instructions that are executable by the digital

processing apparatus for performing method acts for outputting lower-level code to process multi-bit, signed

data elements. The lower-level code includes computer readable code means for packing at least first and

second data elements into a single register, and computer readable code means for processing the elements

simultaneously. The elements are permitted to interact with each other (such as by, e.g., carries and

borrows).

The reference numerals and page and figure numbers above are incorporated in the summary of Claim

11, which recites a method that includes defining at least one compiler directive, instructions, or configuration

file for a compiler (page 5, penultimate paragraph of summary) that defines an input precision for at least

one data element and/or multiple data sources of respective data elements to be packed into a common register

and operated on by an algorithm simultaneously with each other (id.) The data elements can carry from each

other, and a carry propagating left without a previous borrow having occurred cannot happen and further a

borrow can only follow a borrow in underflow conditions such that in any one processing cycle, at most one

borrow occurs from each element in the register (page 17, top of page).

(6) Grounds of Rejection to be Reviewed on Appeal

1169-d,API

FROM ROG-ITZ 619 338 8078

CASE NO.: BLD9-2000-0060-US2

Serial No.: 09/693,090

December 7, 2004

Page 4

PATENT

Filed: October 20, 2000

(a) Claims 6, 9, 11-18, 21, 23, 25, 26, and 29 have been rejected under 35 U.S.C. §112,

first paragraph, for lacking adequate written description.

(b) Claims 1-6, 11-21, and 23-26 have been rejected under 35 U.S.C. §102 as being

anticipated by [FiD98].

(c) Claims 5 and 29 have been rejected under 35 U.S.C. §103 as being unpatentable over

[FiD98] in view of Staugaard, Jr.

(d) Claims 7-10, 22, 27, and 28 have been rejected under 35 U.S.C. §103 as being

unpatentable over [FiD98] in view of Mendel, USPN 6,080,204.

(7) Argument

As an initial matter, it is noted that according to the Patent Office, a new ground of rejection in an

examiner's answer should be "rare", and should be levied only in response to such things as newly presented

arguments by Applicant or to address a claim that the examiner previously failed to address, 69 Fed. Reg.

155 (August 2004), see, e.g., pages 49963 and 49980. Furthermore, a new ground of rejection must be

approved by the Technology Center Director or designee and in any case must come accompanied with the

initials of the conferees of the appeal conference, id., page 49979.

(7a) Commencing with the written description rejection which is predicated on the allegation that the

amendment to the specification added new subject matter when it clarified that "input precision" means the

initial precision of individual data elements prior to after simultaneous operation, on page 4 in the paragraph

immediately following the paragraph that was amended, it is disclosed that "when the output precision is to

1169-6, AP1

FROM ROGITZ 619 338 8078

CASE NO.: BLD9-2000-0060-US2

Seriai No.: 09/693,090

December 7, 2004

Page 5

PATENT Filed: October 20, 2000

be determined from the input precision by the compiler, the compiler counts the number and types of

operations to be performed on the data, extending the input precision by one bit for each addition or

subtraction and by sufficient bits to accommodate multiplication operations, and by one bit when necessary

to ensure that the maximum magnitude negative number that can be represented by a data element is one

larger than the maximum negative number that can be represented in the output precision" (emphasis mine).

Thus, as stated in this paragraph the input precision does indeed reflect the initial precision of individual data

elements after simultaneous operation has been accounted for. It appears that the new matter objection and

related written description rejections are incorrect.

(7b) The anticipation rejection is perhaps even easier to overcome, because under the examiner's own

admissions as to how he is reading the claims, they are patentable over FiD98. More specifically, the

examiner reasons that because the claims use permissive language (e.g., Claim 1 recites that a carry and/or

a borrow "may" occur between data elements in a register), this means that the limitations are optional -

which they are, in marked contrast to FiD98. That is why the inventor's prior Rule 132 declaration must

not be so facilely brushed off. By its explicit terms, which the examiner readily concedes, Claim 1 requires

that carries and/or borrows "may" occur, whereas in FiD98, the separate elements being processed in a single

register are not allowed, ever to interact with each other by, e.g., carrying or borrowing. Instead, in the

FiD98 system the elements ("fields") are isolated from each other (page 5, top, discussing partitioned

operations) either by "spacer bits" (page 6, particularly last paragraph) or by using additional instructions

(pages 7 and 8). Nowhere does the FiD98 paper suggest otherwise. In contrast, the present invention as now

claimed makes such interaction permissible.

1169-A.API

FROM ROGITZ 619 338 8078

CASE NO.: BLD9-2000-0060-US2

Serial No.: 09/693,090 December 7, 2004

Page 6

PATENT Filed: October 20, 2000

Thus, it is this very permissivity that the examiner admits is in the claims that makes them patentable

over FiD98. There is simply no way to regard a reference in which an action is always forbidden to be the

same as a claimed invention that permits the action to occur. Stated differently, in FiD98, as has been

established by the Rule 132 declaration it is quite incorrect to state that a carry or borrow "may" occur, in

contrast to Claim 1, when in fact such features can never occur in the FiD98 system.

Claims 5 and 29 have been rejected under 35 U.S.C. §103 as being unpatentable over FiD98 in view (7c)

of Staugaard, Jr., used as a teaching of non-compiled comments with the proferred suggestion to combine

being "to provide additional documentation without changing the behavior of a program". Nowhere,

however, is any prior art citation to this suggestion made, and more importantly, nowhere does FiD98 suggest

that providing additional documentation is a problem. That means that the requisite prior art motivation to

combine Staugaard, Jr. with FiD98 is missing, because whatever reason Staugaard, Jr. gives for using

comments, there has been no showing relating that reason to anything in FiD98. Likewise, Appellant

respectfully asserts that no prior art reason or motivation has been pointed to for combining Mendel with

FiD98.

Claims 7-10, 22, 27, and 28 have been rejected under 35 U.S.C. §103 as being unpatentable over (7d)

FiD98 in view of Mendel, used as a teaching of computer program storage devices. For reasons advanced

above, even if Mendel were to be combined with FiD98, the claims would not obtain.

### APPENDIX A - APPEALED CLAIMS

1. A computer system, comprising:

a compiler receiving higher-level code and outputting lower-level code to enable a processor to simultaneously process multiple multi-bit data elements in a single register, the logic of the lowerlevel code including:

establishing at least first and second signed, multi-bit data elements in at least a first register; and

simultaneously processing the elements, wherein at least one of: a carry, and a borrow, may occur between data elements in a register.

- 2. The computer system of Claim 1, wherein the compiler accesses at least one of: a compiler directive, a flag, or a configuration file, to decide when to make elements independent of each other.
- 3. The computer system of Claim 1, wherein a first element is provided from a first data set and a second element is provided from a second data set different than the first.
- 4. The computer system of Claim 1, wherein the compiler allocates a respective output precision in a register for each data element to be processed in the register during a single cycle.
- 5. The computer system of Claim 1, wherein the compiler receives instructions not to compile a predetermined portion of code received by the compiler.

**PATENT** 

Filed: October 20, 2000

6. The computer system of Claim 1, wherein an output precision or an input precision is defined

by means of a compiler directive, or a configuration file, or a variable definition.

7. A computer program device comprising:

a computer program storage device readable by a digital processing apparatus; and

a compiler program on the program storage device and including instructions executable by the digital

processing apparatus for performing method acts for outputting lower-level code to process multi-bit, signed

data elements, the lower-level code comprising:

computer readable code means for packing at least first and second data elements into a single

register; and

computer readable code means for processing the elements simultaneously, the elements being

permitted to interact with each other.

8. The computer program device of Claim 7, further comprising:

flag means indicating whether a precision should be checked in at least one cycle.

9. The computer program device of Claim 7, further comprising:

compiler directive means for defining an input precision.

10. The computer program device of Claim 7, further comprising:

FROM ROGITZ 619 338 8078

Page 10

PATENT

Filed: October 20, 2000

compiler directive means for defining multiple data sources of respective data elements to be

packed into a common register and operated on by an algorithm simultaneously with each other.

11. A method, comprising:

defining at least one compiler directive, instructions, or configuration file for a compiler

defining at least one of:

an input precision for at least one data element; and

multiple data sources of respective data elements to be packed into a common register and

operated on by an algorithm simultaneously with each other, wherein the data elements can carry

from each other, and wherein a carry propagating left without a previous borrow having occurred

cannot happen and further wherein a borrow can only follow a borrow in underflow conditions such

that in any one processing cycle, at most one borrow occurs from each element in the register.

12. The method of Claim 11, wherein the compiler determines first and second precisions to be

allocated in a single register to hold respective first and second signed data elements, and the compiler

generates a lower-level code from a higher level code to undertake method acts comprising:

packing the elements into the register; and

operating on the elements.

13. The method of Claim 12, wherein the register sends plural data elements simultaneously to

at least one computational subsystem.

FROM ROGITZ 619 338 8078

Serial No.: 09/693,090

December 7, 2004

Page 11

PATENT Filed: October 20, 2000

14. The method of Claim 13, wherein the operation is a multiplication by a constant or by a

variable of known precision, or an addition, or a shift-left logical, or a subtraction, or a bitwise AND, or a

bitwise OR.

15. The method of Claim 14, wherein the elements are independent of each other as defined by

the compiler directive or configuration file.

16. The method of Claim 15, wherein the first element is provided from a first data set and the

second element is provided from a second data set different than the first.

17. The method of Claim 12, wherein the first element is a first partial element having a related

second partial element established in a second register, and the lower-level code causes the first and second

partial elements to be combined after processing.

18. The method of Claim 12, wherein the act of determining first and second precisions includes

determining the precisions such that the maximum negative number that can be represented in an element is

one larger than the maximum negative number that can be represented in the respective precision.

19. The computer system of Claim 2, wherein the compiler generates instructions to pack multiple

data elements from respective data sources into, a common register to be operated on by an algorithm

simultaneously with each other.

PATENT

20. The computer system of Claim 19, wherein the first element is a first partial element having

a related second partial element established in a second register, and the lower-level code output by the

compiler causes the first and second partial elements to be combined after processing.

21. The method of Claim 11, wherein the compiler directive, instructions, or configuration file

embodies instructions to compile predetermined portions of code received by the compiler to be executed

simultaneously on packed data.

22. The computer program device of Claim 7, further comprising:

means for indicating whether a precision should be checked;

means responsive to the means for indicating for checking that the packed elements do not

overflow or underflow or achieve a maximum magnitude negative number representable in the

precision; and

means for, when packed elements overflow or underflow or achieve a maximum magnitude

negative number representable in the precision in a cycle, undertaking wrap or saturation in the

elements to prevent corruption of other data elements in a register, or signalling an error to be

handled by an error-handling routine in the program.

23. The computer system of Claim 4, wherein the compiler determines the output precision based

at least in part on an input precision.

PATENT Filed: October 20, 2000

24. The computer system of Claim 4, wherein the compiler receives, as input, the output

precision.

25. The computer system of Claim 23, wherein the compiler adds a bit of precision if the

maximum magnitude negative number that is required for the data during processing is the maximum

magnitude negative number that can be represented in the respective precision.

26. The computer system of Claim 23, wherein the compiler adds at least one bit of precision

based at least in part on an operation on a data element.

27. The computer program device of Claim 7, further comprising means for adding a bit of

precision if the maximum magnitude negative number that is required for the data during processing is the

maximum magnitude negative number that can be represented in the respective precision.

28. The computer program device of Claim 7, further comprising means for adding at least one

bit of precision based at least partially on an operation on a data element.

29. The method of Claim 11, further comprising defining instructions not to compile a

predetermined portion of code received by the compiler.

## **RULE 132 DECLARATION**

Commissioner of Patents and Trademarks Washington, DC 20231

Dear Sir:

## I, Joan L. Mitchell, Ph.D., declare as follows:

- 1. I am one of the present inventors and have been an IBM Fellow since May 2001. I have been elected to IBM's Technical Academy and have been designated an IBM Master Inventor, having been a named inventor on over fifty issued U.S. patents and having received 25 Plateau Awards (one for every four applications filed). I am also an IEEE Fellow and was editor in the late '80s and early '90s for the JPEG Committee. I have been informed that I will be inducted this October into the National Academy of Engineering, Section 5 (Computer Science and Engineering).
- 2. I have reviewed the paper referred to in the Office Action as FiD98 (the "SWAR" paper).
  The SWAR technology requires that the separate elements (sometimes referred to in the SWAR paper as "fields") be kept separate from each other and not interact. In the SWAR terminology, the elements in a

1169-6.DEC

2004/06 /02 15:50:51

Pages: 3/3

CASE NO.: BLD9-2000-0060-US2

Serial No.: 09/693,090

June 2, 2004 Page 2

THETAN Filed: October 20, 2000

in a register remain "partitioned". The ways partitioning is achieved by and large can be found on pages 5-7 of the SWAR paper.

- In contrast, the present claims permit interaction (by, e.g., borrowing and carrying) between the data elements. In our specification, we refer to the data elements under these conditions as being "packed". In effect, using terminology from the SWAR paper in the context of our invention, we use unpartitioned instructions on packed data, whereas this is not permitted by the SWAR authors.
- I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and betiaf are believed to be true; and further that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United State Code and that such willful, false statements may jeopardize the validity of the application or any patent issued thereon.

Doan Mitchell Dr.
